

Laser alignment of molecules with laser pulses

Henrik Stapelfeldt

Department of Chemistry, University of Aarhus, Denmark, (henriks@chem.au.dk)

This talk will discuss how the spatial orientation of molecules in the gas phase can be controlled by moderately intense, polarized laser pulses. The basic physical principles of alignment will be explained including the crucial roles of the laser intensity, the polarization state, the turn-on time, the pulse duration, and the rotational state of the molecules. Examples of recent and prospective applications of aligned molecules will be discussed.
